Abstract
The aim of this study was to investigate by histological techniques the structure of urethral epithelium in lambs. In this study, we harvested several fragments (prostatic, membranous and cavernous) from urethra from 5 merino's lambs of 3 months old. The first anatomical segment, the prostatic urethra, is lined by a urinary epithelium. The intermediary layer of this epithelium is formed of 5-6 rows of oval cells. The second segment of urethra has the same type of epithelium but the intermediary layer is formed of 6-7 rows of oval cells. In the last anatomical segment, the penile urethra, the epithelium is the same, but the intermediary layer has 3-4 rows of oval cells. In lambs, the urethra is lined by urinary epithelium. The urethral epithelium does not have the same thickness in all segments. The thinner epithelium is in the cavernous urethra, the thicker is the membranous urethra.

Keywords: epithelium, lamb, urethra.

Introduction
The urethra is longer in males and has the following segments: prostatic urethra, membranous urethra and cavernous urethra (Gal and Miiclăuș, 2013). Generally in adult's males, the first segment is represented by urothelial type epithelium, the second segment has stratified columnar epithelium and in the last segment, the epithelium becomes non-keratinized squamous stratified (Lesson and Lesson, 1971). In literature is mentioned the structure of the epithelium in adult animals and we did not find any studies made on young animals. Some authors affirm that the urothelium and the urethral epithelium have same embryologic origin, but the genes expressed by the cells present in the urothelium are not the same with those expressed by the cells present in the urethral epithelium (de Graaf et al., 2017). In humans, for the urethral reconstruction is used the urothelium or the oral mucosal cells, but the urethral grafts are not fully successful (de Kemp et al., 2015). It is very important to know the structure of urethral epithelium in young animals in reconstruction of the urethral wall after different pathological situations, such as urethral stricture or congenital disorders.

The aim of this study was to investigate by histological techniques the structure of urethral epithelium in lambs.

Materials and methods
In this study we used 5 merino's lambs of 3 months old. We harvested fragments from urethra, from 3 different zones: prostatic, membranous and cavernous. The samples were fixated in Stieve solution, dehydrated in ethylic alcohol, clarified in n-butanol and embedded in paraffin. The samples were sectioned at 5 µm thickness and stained using Goldner's trichrome method.

Results and discussions
The first anatomical segment, the prostatic urethra, is lined by a urinary epithelium. The intermediary layer of this epithelium is formed by 5-6 rows of oval cells (fig. 1). The second segment of urethra has the same type of epithelium but the
intermediary layer is formed by 6-7 rows of oval cells (fig 2). In the last anatomical segment, the penile urethra, the epithelium is also the same, but the intermediary layer has 3-4 rows of oval cells (fig.3). Our results show differences between the structures of the urethral epithelium described by others authors (Lesson and Lesson, 1971; Gal and Midăuș, 2013). This differences of the epithelium structure which lined the urethra is probably typical for young animals. As some authors assert, the presence of the urothelium in young animals urethra (3 months old) may be found because the urethral epithelium has the same embryological origin as the bladder (de Graaf et al., 2017), and probably with the sexual development, this epithelium is transformed.

Conclusions

In lambs, the urethra is lined by urinary epithelium. The urethral epithelium does not have the same thickness in all segments. The thinner the epithelium in the cavernous urethra, the ticker the membranous urethra is.
