# YIELD RESPONSE OF THE LAYING HYBRIDS TO THE MODIFIED COOPS REARING SYSTEM

# Usturoi M.G., I. Vacaru-Opriș, R.M. Radu-Rusu, Cristina Radu-Rusu, D. Simeanu, A. Usturoi

University of Agricultural Sciences and Veterinary Medicine, Iasi email: umg@univagro-iasi.ro

Key words: eggs, yield, alternative system, laying hybrid

**Abstract.** The management conditions provided to the fowl having not free access to hall floor (Lc,  $L_1exp$  and  $L_2exp$ ) allowed the expression of the used hybrid (Lohmann Brown) potential. Thus, control group yield counted 325.05 eggs, compared to just 311.34 eggs, produced by the  $L_3exp$  (hens with free access on hall floor). Mortality has been correlated with the brooding density (7.46÷9.57% in experimental groups and 11.66% in Lc one). Shell was found thicker in  $L_3exp$  group (0.369÷0.448 mm), as well as its breaking strength (0.337÷0.348 kg f/cm<sup>2</sup>). Microbial load of the shell gradually increased, especially in  $L_3exp$  group (148.62÷258.94 germs/cm<sup>2</sup>, compared with 106.31÷106.61 germs/cm<sup>2</sup>).

# INTRODUCTION

Almost 75% of the worldwide laying hens are reared in coop batteries, in some different brooding density conditions, as related to the country or region. The amount of hens, which should populate one single coop, is a quite controversial problem, knowing that selecting fowl for eggs yield improvement led to an increase of their aggressive temperament. Starting from 2012, the egg producers from the European Union will be constrained by law enforcements to use modified coops or other alternative systems in laying hens husbandry, knowing that conventional coops will cease to be used as legal or accepted production facilities. In Romania, the rearing of chicken laying hybrids uses almost exclusively the conventional coops batteries as accommodation manner. The replacement of this system by another one, would lead to the bankruptcy of an economic field that is still profitable.

# MATERIAL AND METHODS

The "Lohmann Brown" hens we used as biological material (1731 hens) have been randomly distributed to 4 groups and reared in unmodified coops (Lc), modified coops ( $L_1$ exp and  $L_2$ exp) and having free access all over the hall ( $L_3$ exp), as well (*tab. 1*).

Table 1

Notice	Experimental groups

\* standard coops \*\* modified coops \*\*\* feeding+watering coops and laying+resting coops

Several parameters and indexes have been assessed during the study:

Body weight	body weight dynamics
Eggs yield	eggs yield dynamics; laying intensity
Feeding	average feed intake (g/hen/day); feed intake (g feed/egg)
Health status	flock looses dynamics; flock looses casualty
Morphological and physical eggs quality indexes	morphological anomalies (%); eggs weight (g); shell thickness (mm); eggshell breaking strength (kg $f/cm^2$ )
Microbiological eggs quality indexes	microbial load (germs/cm <sup>2</sup> of eggshell)

All groups have been accommodated within the same shelter, divided in four compartments, identical as size and technological conditions.

# **RESULTS AND DISCUSSIONS**

**1. Body weight dynamics**. The values for this parameter were slightly equal at all 4 groups, during the beginning of our studies ( $20^{th}$  week) ( $1575.31 \div 1577.82g$ ), whilst the first major differences occurred when fowl reached peak of production ( $28^{th}$  week). Thus, hens weight reached 1901.69±40.86g in Lc, de 1870.53±38.07g in L<sub>1</sub>exp, 1868.58±45.01g in L<sub>2</sub>exp and only 1859.40±45.37g in L<sub>3</sub>exp. At the end of our research ( $80^{th}$  week), the differences became more pronounced, reaching 2125.13±69.71g at the control group; 2087.83±67.95g at L<sub>1</sub>exp group; 2083.03±66.99g at L<sub>2</sub>exp group and 2030.29±69.64g at the L<sub>3</sub>exp one.

**2. Eggs yield and laying intensity** (*tab. 2*). Classical rearing version (4 hens/unmodified coop) proven to generate the highest eggs yield meaning 325.05 eggs/hen. It followed the  $L_1exp$  (319.09 eggs/hen), then  $L_2exp$ , with 316.32 eggs/hen. The production reached only 311.34 eggs/hen within the  $L_3exp$  (free access over the whole rearing compartment), probably due to the energy and protein feed expenditures for the supplementary movements. The highest values of the laying intensity have been reached during the 28<sup>th</sup> week of life, meaning 91.56% in Lc, 89.97% in  $L_1exp$ , 89.88% in  $L_2exp$  and 88.35% in the  $L_3exp$  one.

**3. Feed consumption** (*tab. 3*). Several mixed feed recipes have been used to feed the fowl, depending on the energy and proteins requirements, as related to the laying intensity. Lowest values for daily feed intake ( $106.32 \div 115.18$  g/hen) and for FCR ( $126.29 \div 141.65$  g/egg) have been observed during the first feeding period (20-45 weeks), then increased, during the 46-65 weeks period ( $111.99 \div 115.66$  g/hen and  $146.48 \div 158.38$  g/egg) and mostly across the last feeding stage (66-80 weeks), when daily average intakes reached  $119.74 \div 135.60$  g/hen and FCR was calculated values were found within the  $191.29 \div 231.75$  g/egg interval. All over the studied period the best values for feed intake have been noticed at the control group (112.63g/hen-average daily intake and 145.34g/egg-FCR), while the poorest results were achieved by the hens belonging to the L<sub>3</sub>exp (120.51g/hen and 164.38g/egg).

Feed intake and Feed Conversion Rate

**4.** Flock looses. This parameter reached 0.23% at Lc and L<sub>2</sub>exp and 0.46% at L<sub>1</sub>exp and L<sub>3</sub>exp, at the end of the 20<sup>th</sup> week of life, being caused by transportation and acclimatization stress and also by the hierarchic social fights. Then, looses significantly decreased, even leading to the lack of mortality, excepting during the cold season (36-41 weeks), when mortality reached 0.23÷0.47%/week or during the warm one (July-August), when mortality reached 0.24÷0.49%/week, because the outer environment temperature influenced the microclimate of the hall which was not endorsed with climate control system. Over the whole period flock looses values were found different between groups, depending on the applied technology. Thus, the lowest value (7.46%) was observed in L<sub>3</sub>exp group, whose hens beneficiated of movement freedom all over the compartment. Then, next ascending values were calculated for L<sub>2</sub>exp group (1000cm<sup>2</sup> coop floor/hen)-8.22% mortality, for L<sub>1</sub>exp group (600cm<sup>2</sup> coop floor/hen)-9.57% mortality and for the control one-11.66%.

**5.** Proportion of eggs presenting morphologic anomalies. Broken eggshells highly occurred during laying beginning  $(0.60\div0.99\%)$ , followed then by other anomalies, such as: shell less eggs  $(0.15\div0.22\%)$ , malformed shells  $(0.16\div0.18\%)$ , twin yolks eggs  $(0.06\div0.08\%)$  and also the eggs without yolk  $(0.02\div0.04\%)$ . During laying peak the proportion of broken shell eggs decreased  $(0.31\div0.72\%)$ , but also increased the malformed shells proportion  $(0.33\div0.35\%)$ , the same situation occurring also during the plateau stage  $(0.50\div0.81\%)$  eggs with broken shell and  $0.39\div0.41\%$  eggs with malformed shell). When hens approached the end of the laying period, most of the eggs with anomalies presented broken shells  $(1.18\div1.59\%)$ , then malformed shells  $(0.62\div0.65\%)$  and shell less eggs  $(0.27\div0.28\%)$ .

**6. Eggs weight** (*tab. 4*). The weight of the eggs issued from all four groups was slightly similar during laying onset  $(46.78 \div 47.01 \text{ g})$ , during peak  $(59.96 \div 60.17 \text{ g})$ , plateau  $(62.91 \div 63.04 \text{ g})$  and even when laying period ended  $(68.24 \div 68.51 \text{ g})$ .

**7. Shell thickness**. The lowest values of the eggshell thickness were observed at the eggs provided by those hens having the best laying intensity (Lc)  $(0.354 \div 0.440 \text{ mm})$ , while those birds with the lowest eggs yield (L<sub>3</sub>exp), presented the thickest shell  $(0.369 \div 0.448 \text{ mm})$ .

8. Egg breaking strength (*tab. 5*). The data we acquired suggest that the best strength of the eggshell was observed during laying onset with different values for each group: 0.340 kg  $f/cm^3$ -Lc; 0.342 kgf/cm^3-L\_1exp; 0.343 kgf/cm^3-L\_2exp and 0.348 kgf/cm^3-L\_3exp. During laying peak, shell stiffness varied between 0.330 kgf/cm<sup>3</sup> (Lc) and 0.339 kgf/cm<sup>3</sup> (L\_3exp), while during plateau stage, it reached values between 0.329 kgf/cm<sup>3</sup> (Lc) and 0.337 kgf/cm<sup>3</sup> (L\_3exp). The worst results for the eggshell breaking strength were noticed when laying ceased, reaching thus: 0.325 kgf/cm<sup>3</sup> in Lc; 0.326 kgf in L<sub>1</sub>exp; 0.327 kgf in L<sub>2</sub>exp and L<sub>3</sub>exp. Table 5

Eggshell breaking strength (n=30)

**9. Microbial shell load** (*tab. 6*). During the laying beginning ( $20^{th}$  week), microbial shell load reached 112.78±3.906 germs/cm<sup>2</sup> at the Lc, 110.4±3.671 germs/cm<sup>2</sup> at L<sub>1</sub>exp, 106.31±3.418 germs/cm<sup>2</sup> at L<sub>2</sub>exp and also 148.62±6.097 germs/cm<sup>2</sup> at the L<sub>3</sub>exp. Statistically speaking, significant differences occurred between L<sub>2</sub>exp and Lc and L<sub>1</sub>exp, while between L<sub>3</sub>exp and the other groups (Lc, L<sub>1</sub>exp and L<sub>2</sub>exp), the differences proved to be high significant.

Table 6

During laying peak, ( $28^{th}$  week), germs amount on each cm<sup>2</sup> of shell increased, the values varying between 120.14±3.372 (L<sub>2</sub>exp group) and 187.56±8.663 (L<sub>3</sub>exp group). Statistical analysis revealed the same situation (significant differences between L<sub>2</sub>exp and Lc, L<sub>1</sub>exp groups, respectively high significant between L<sub>3</sub>exp and the other groups). The eggs harvested during the plateau stage ( $37^{th}$  week) had higher germs amounts that varied within the 134.98±4.441/cm<sup>2</sup> (L<sub>2</sub>exp) and 221.17±10.836/cm<sup>2</sup> (L<sub>3</sub>exp) limits. Statistically, the differences were found similar to those recorded during the previously control periods. The highest levels of microbial contamination have been noticed when laying almost ceased ( $80^{th}$  week), meaning: 152.61±4.957 germs/cm<sup>2</sup> shell at the L<sub>3</sub>exp group. Significant differences occurred between L<sub>2</sub>exp and Lc, L<sub>1</sub>exp groups and also high significant ones between L<sub>3</sub>exp and Lc, L<sub>1</sub>exp groups.

# CONCLUSIONS

Several conclusions issued from the researches:

**Body weight** dynamics was found in accordance with the "Lohmann Brown" standard weight curve. However, there were some differences between groups, given by the presence/absence of the movement freedom. The optimized management applied to the groups without free access in the hall (L<sub>1</sub>exp, L<sub>2</sub>exp and Lc) provides to the fowl the opportunity to express the yielding potential, *average yields* of 316.32÷325.05 eggs/hen being achieved, as compared to the average value noticed for the L<sub>3</sub>exp group (311.34 eggs/hen). Egg production values influenced *feed intake*, the best FCR value being calculated for the Lc (134.34g/egg) while the less competitive (164.38g/egg) was observed in the L<sub>3</sub>exp. *Mortality* 

*rate* was 0.76-4.20% lower at the  $L_3 exp$  (free access in rearing compartment), as compared to the other groups, which provided different rearing floor surface in the coops.

*Eggs weight* was ascending from the laying beginning toward its end, without the occurrence of statistic significance between groups. Shell thickens was reversal correlated to the laying intensity, being higher  $(0.369 \div 0.448 \text{mm})$  at the eggs issued from the group with the poorest yield (L<sub>3</sub>exp); consequently, the best values for the *shell breaking strength*  $(0.337 \div 0.348 \text{ kg f/cm}^2)$  were measured within the same group. Meanwhile, higher germs load was noticed in the same group (L<sub>3</sub>exp), respectively 39.9-69.7% more than the other groups, because the hens spend more time on the layer between battery lines or laid straight on it.

Basing on those previously specified aspects, we still recommend the maintenance of the superintensive rearing system in Romania, at least for a few years ahead, using BP-3 batteries with modified coops, in order to allow the accommodation of 5 hens/each coop of  $3000 \text{cm}^2$  (600cm<sup>2</sup>/hen).
